FlowForwarding Warp: How is JVM running SDN Controller

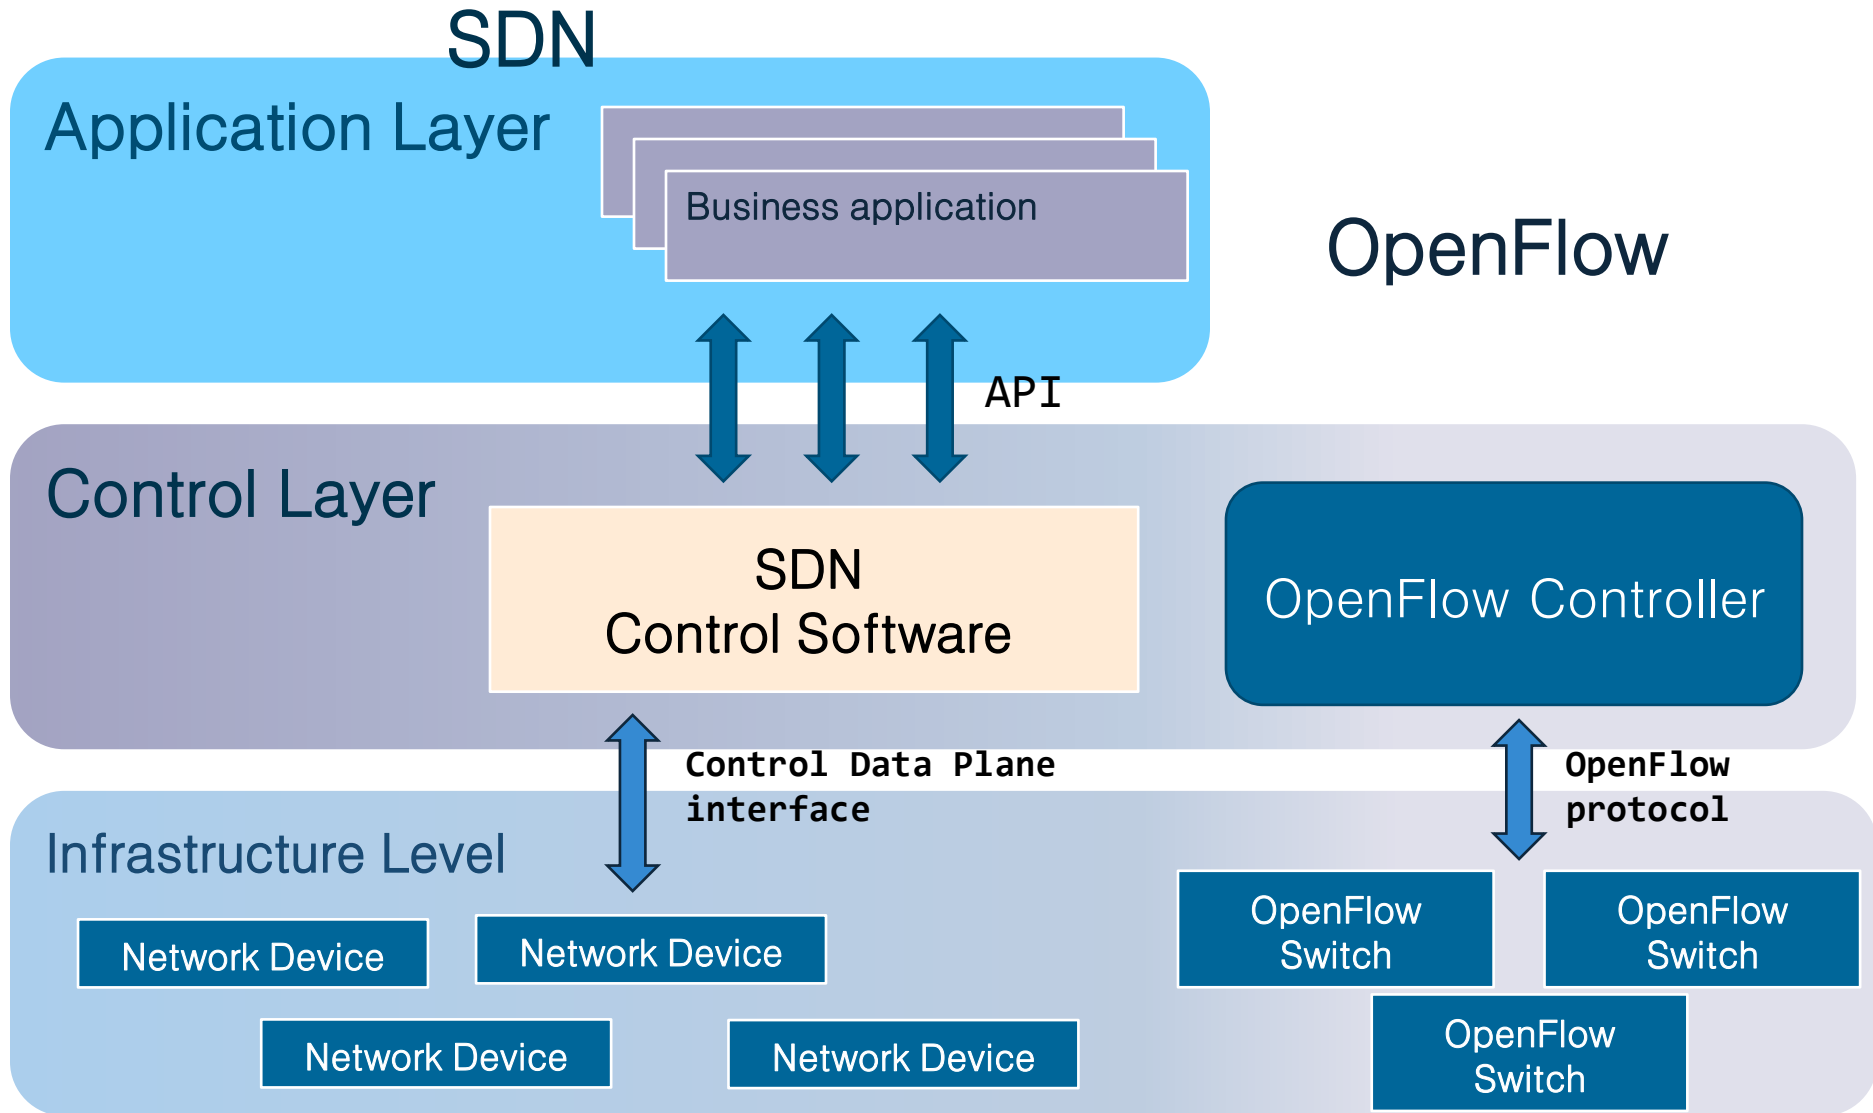

presented by
Dmitry Orekhov

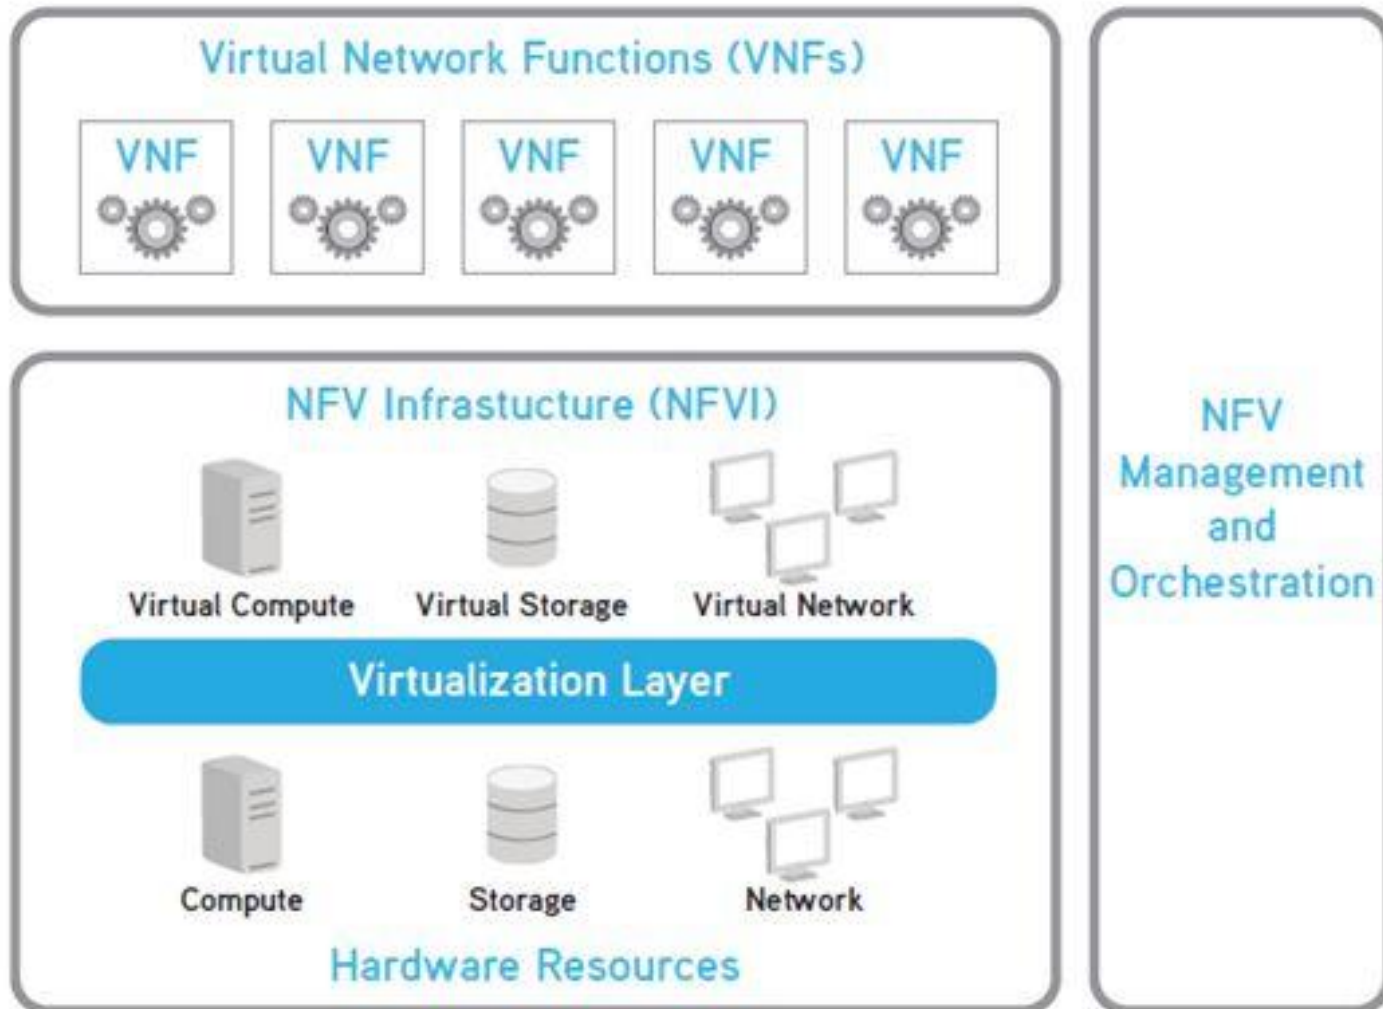

SDN: Concept

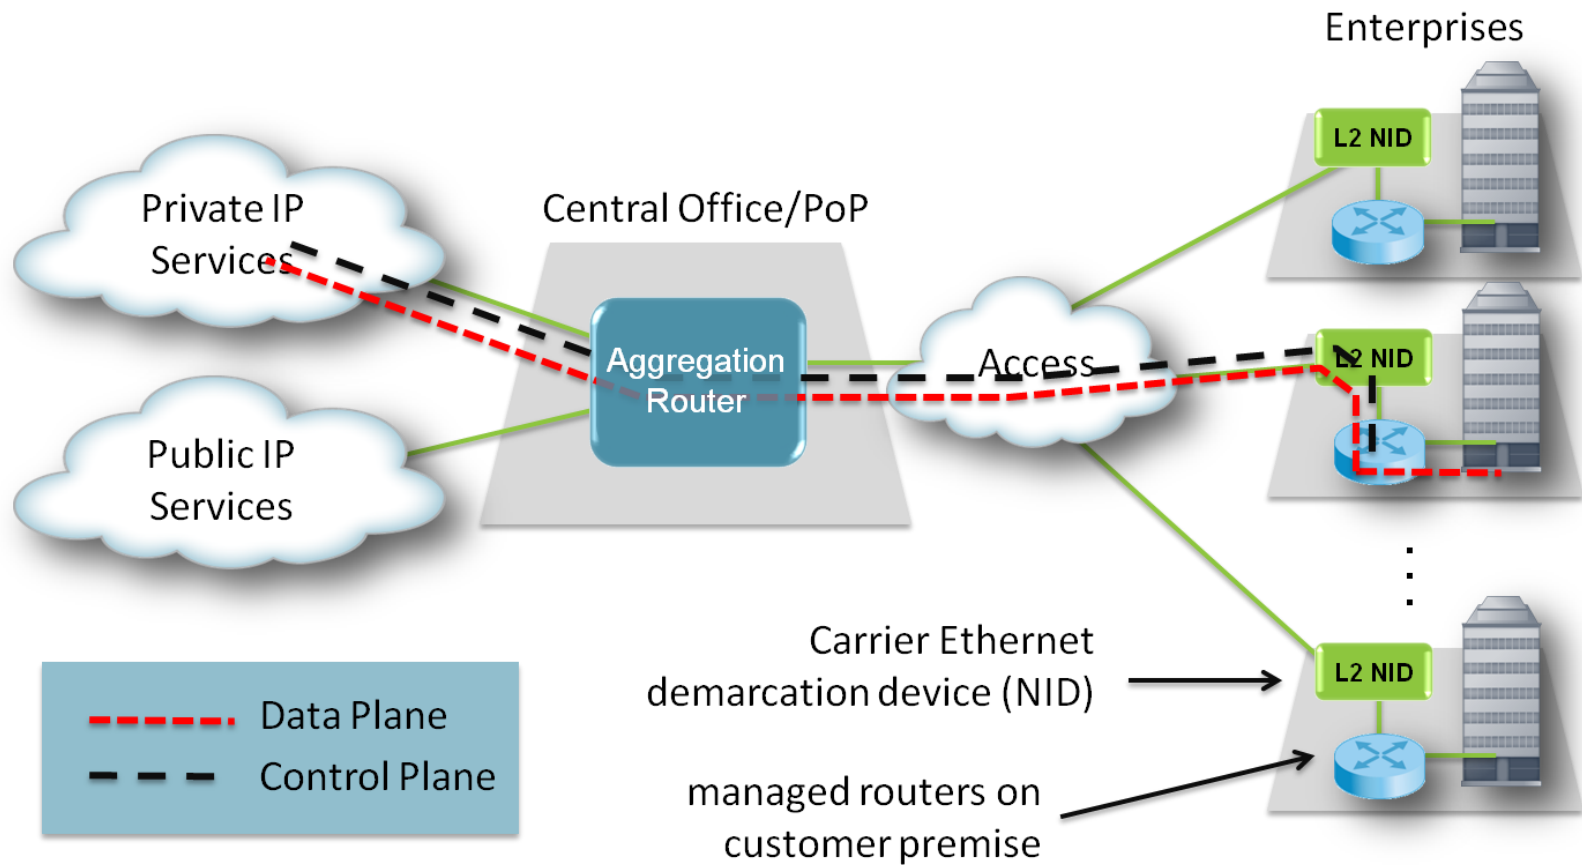

SDN: Big Picture

NFV: Customize Software

NFV and SDN

SDN: Other Cases

- [1] Service Insertions;
- [2] Dynamic WAN rerouting;
- [3] Bandwidth On Demand;

SDN Controller tomorrow

[−]Bad: Each Controller will handle
thousands sessions with Switches

[+]Good: Sessions are fully independent
Sessions are Stateless

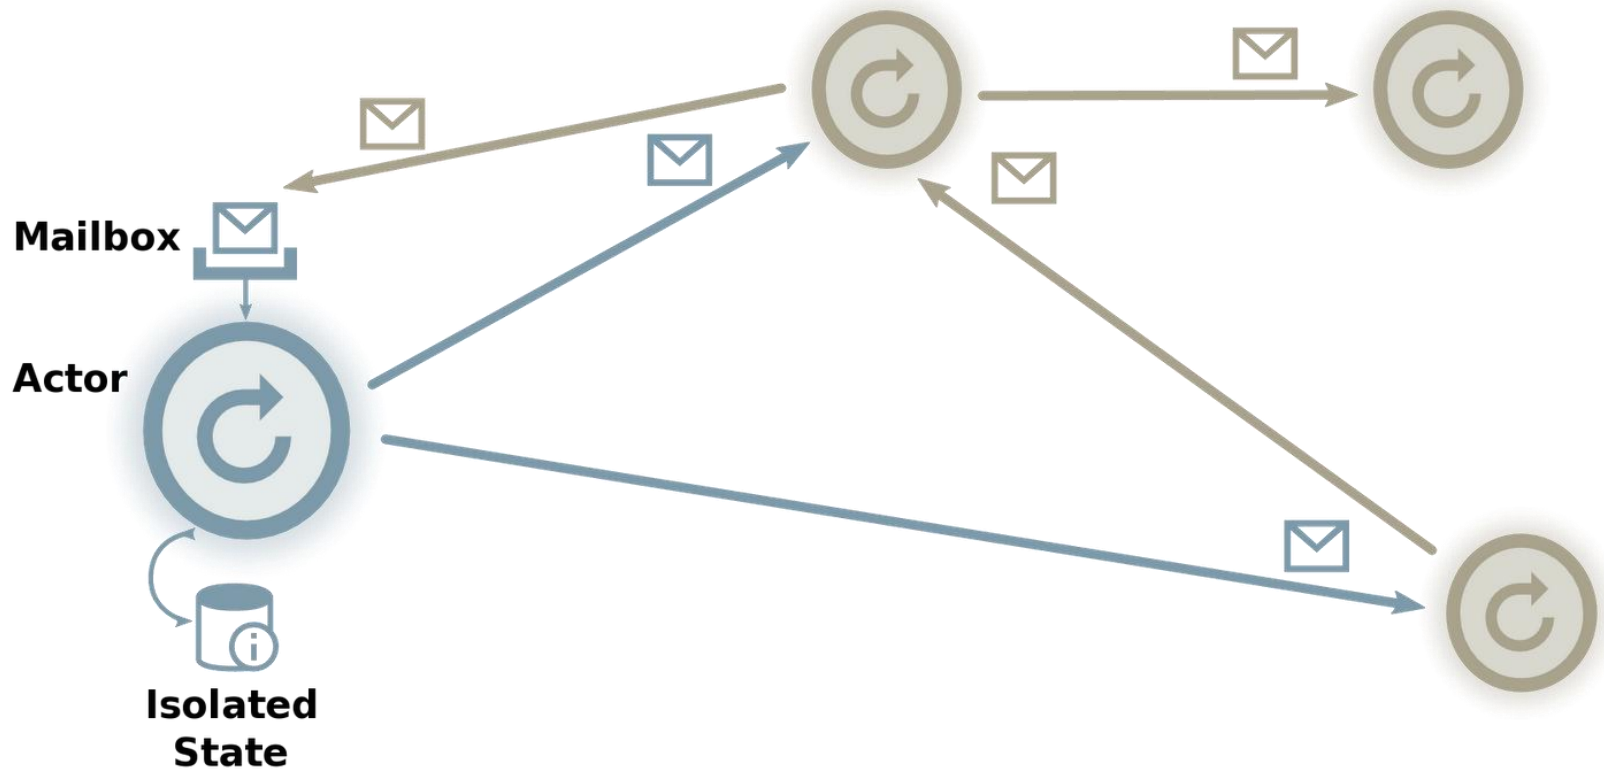

Spawn and Let'em Crash

Spawn and Let'em Crash

Actors Model

Integration

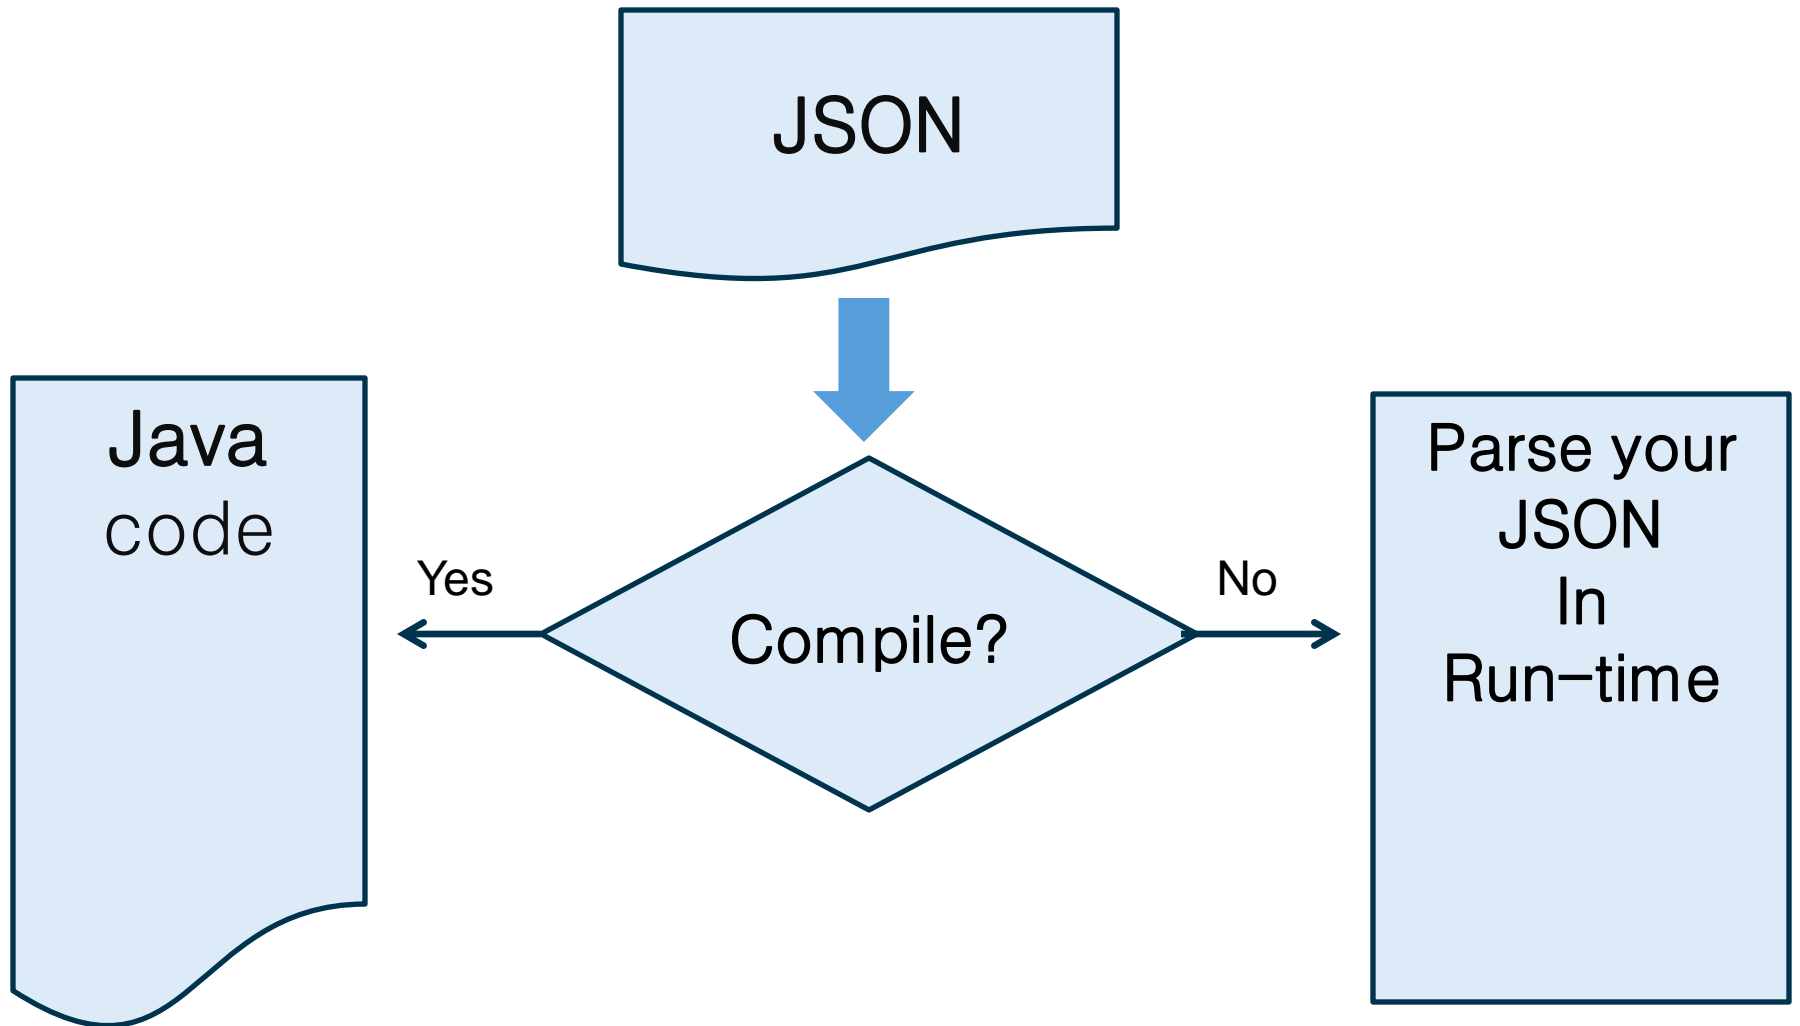

openstackTM
CLOUD SOFTWARE

Why JVM?

- [1] Easy to build Libs and API
- [2] Plenty JVM-based solutions in SDN domain
- [3] Akka and Avro

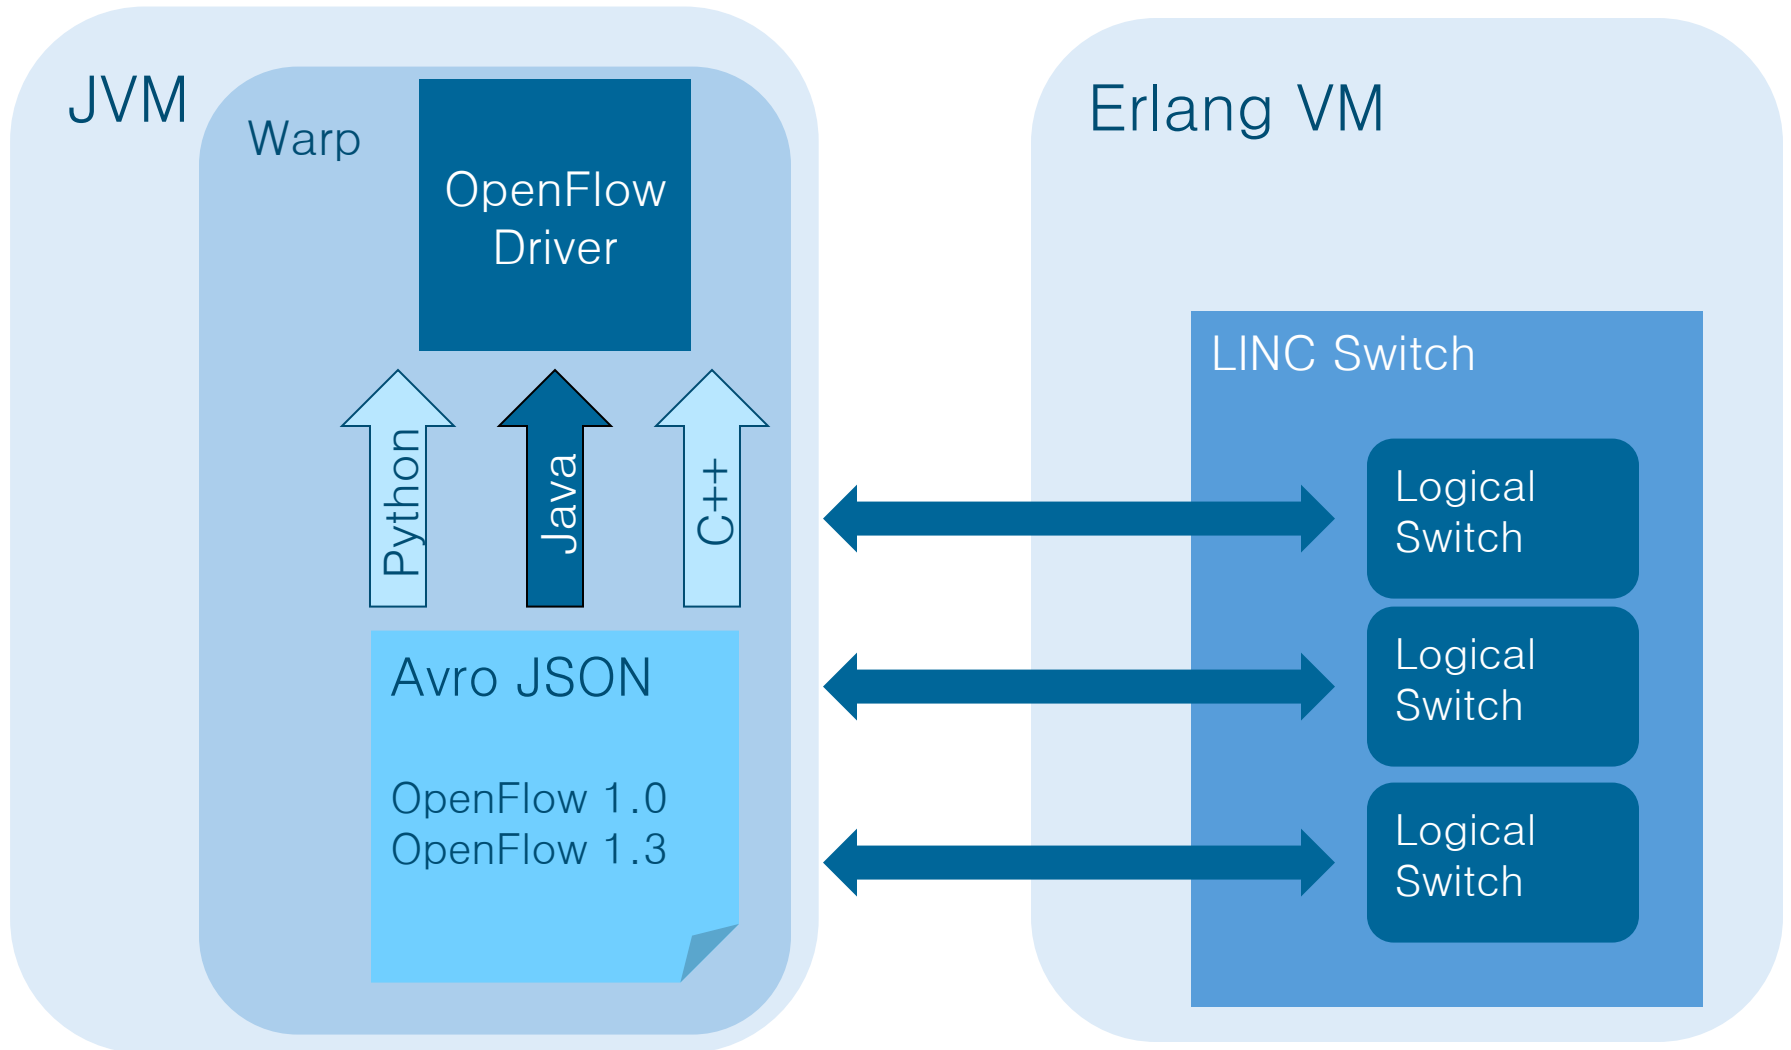

Apache Avro

Apache Features

- You can serialize Data as is, no encoding, no Metadata
- You can do it in Run-time
- Lazy initializations + Caching makes it faster
- Java, C++ and Python API

Warp OpenFlow Driver

Akka: Erlang on JVM

High Performance

50 million msg/sec on a single machine.

Small memory footprint

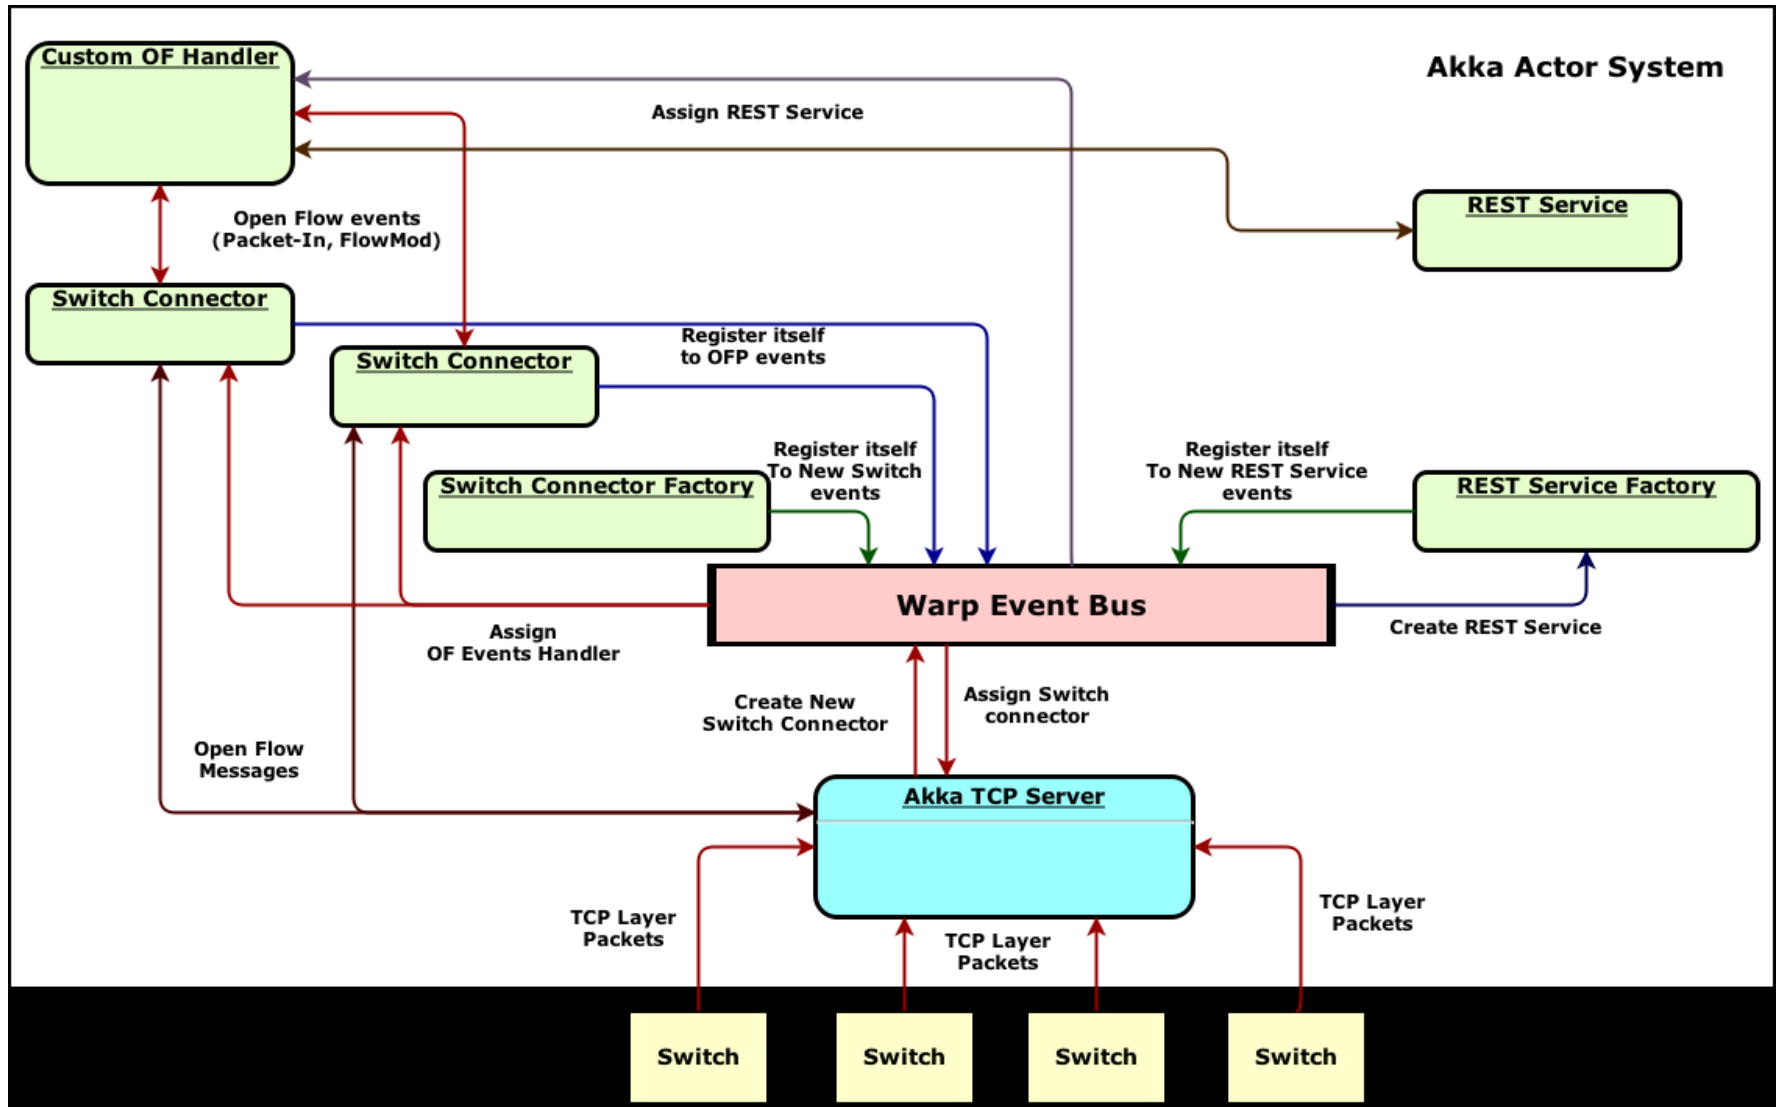

~2.5 million actors per GB of heap.

Elastic & Decentralized

Adaptive load balancing, routing, partitioning and configuration-driven remoting.

Akka: and Event Bus

How it looks like

Preliminary Testing

Environment: 3 workstations, 4 core per one

Running: 500 Logical LINC Switches
on two workstations;
1 Warp controller on the 3rd

Results: Warp holds all 500 connections
(1 hb/10 sec)
500 sessions for 15 sec
1000 OpenFlow message/minute
